PRELIMINARY AMENDMENT

Assistant Commissioner for Patents
Washington, D.C. 20231

Sir:

Prior to examination, please amend the subject application as follows:

IN THE SPECIFICATION

Please amend the specification by inserting before the first line the sentence:

"This application is a national phase of PCT/FR00/01804 which was filed on June 28,
2000, and was not published in English."

REMARKS

Entry of the foregoing amendment to the Specification is requested to comply with the requirements of 37 C.F.R. 1.78(a)(2).

If the Examiner should be of the opinion that a telephone conference would be helpful in resolving any outstanding issues, the Examiner is urged to contact the undersigned.

Respectfully submitted,

BURNS, DOANE, SWECKER & MATHIS, L.L.P.

B13340.3DB

Because of the complexity of the problem, these articles clearly demonstrate the need for perfecting automatic systems capable of learning. Neural methods
30 are therefore often proposed to carry out automatic discrimination of seismic events, but with limitations analysed below. The models suggested most often are multilayer perceptrons with complete connections between successive layers.

35 All these articles seek to determine the origin of the earthquake starting from characteristics extracted solely from the signals. The highest level data (date, time, latitude, longitude, magnitude etc.) are never used for classification. But seismologists know the
40 difficulty of discriminating seismic signals through low level processing alone.

Works by Baumgardt and his colleagues described in document reference [1] are without doubt those which have contributed to making the greatest advances in the
45 search for discriminant parameters.

The variations of the cepstrum, the cepstrum of a signal x being the inverse Fourier transform of the logarithm of the Fourier transform of x , are often used. It can thus be shown that the cepstrum makes it
50 possible to visualise the phenomenon of micro-delays present in the blast signals characterised by a greater variance. The document reference [2] also notes this property, nonetheless pointing out that the absence of this characteristic does not permit any deduction
55 concerning the class of the event.

The ratios of the amplitudes of the different types of waves can also serve as discriminants. The

document reference [3] studies a whole series of
 amplitude ratios (P_n/L_g , P_g/L_g , L_g/R_g). These ratios are
 60 described as being able to provide good discrimination.

The same authors also introduce ratios of spectral
 densities of power of the different types of waves
 detected. Just like the amplitude ratios, these
 discriminants are used by all the studies seeking
 65 discriminants in seismic signals. In order to
 characterise the explosions, ratios have also been used
 for power spectral densities of one wave type, S here,
 for bands of different frequencies, that is to say the
 ratio of the power spectral density of S in the range
 70 1-2 Hz to the power spectral density of this same phase
 in the 7-20 Hz band. The ratio between the power
 spectral densities of the S wave below and above 10 Hz
 is also given as a good separator between explosions
 and earthquakes.

75 The document reference [4] notes that the
 propagation time of signals from a mine has a constant
 time $t_{sg}-t_{pg}$ for a given recording station. This
 propagation time is presented as a potential
 characteristic for a mine, nevertheless remaining less
 80 reliable than the preceding characteristics.

The document reference [5] suggests using the
 presence of the surface wave from earthquakes to
 discriminate them from nuclear explosions at regional
 distances. Characterisation of the presence of a
 85 surface wave is made indirectly by comparing the
 magnitudes m_b and M_s . For two seismic events of the same
 magnitude m_b , the magnitude of the surface wave M_s is
 generally higher in the case of an earthquake because

of the presence of the surface wave than in the case of
 90 an explosion. In fact, this crustal Rayleigh wave
 enters into the calculation of the magnitude M_s and its
 presence is subordinate to the phenomenon of shearing,
 absent in the case of nuclear explosions. Representation
 of the difference $(m_b - M_s)$ as a function
 95 of m_b makes it possible to verify this hypothesis.
 Nevertheless, the calculation of the magnitude M_s
 depends on the periodicity of the signal recorded and
 it is not possible to be rigorous for regional events.
 On the contrary, the presence of a surface wave
 100 corresponding to a sedimentary Rayleigh wave in close
 seismic signals, characterises events of an artificial
 nature. A detection method for this second type of
 surface wave consists of searching for its presence
 directly in the spectrogram of the signal, its
 105 frequency being known (between 0.5 and 1.5 Hz) and its
 supposed time of arrival can be calculated from its
 average speed of propagation and the distance
 separating the epicentre from the recording station.

The systems described in documents of prior art
 110 are not operationally credible for several reasons:

- studies carried out by geophysicists, usually
 rich and detailed concerning proposals for discriminant
 parameters, do not suggest any reliable method for
 automatic exploitation of these parameters.
- 115 • studies carried out by computer specialists
 propose systems that do not take sufficient account of
 the complementarity of data and geophysical knowledge.

Most of prior art studies use data bases of
 seismic events of extremely reduced size, with the

120 consequence that they do not permit correct statistical
learning. Classification is usually carried out on
bases with fewer than one hundred events, as described
in the documents reference [2] and [6]. One of the
biggest bases found in prior art documents comprises
125 only 312 events, as described in document [4]. The
direct consequence is that the margins of error for the
results presented are very high, which cannot provide
great confidence in these results.

The geographic spread of the examples in the data
130 base is a very important element. Most bases group
together events which have taken place in regions of
restricted size (several tens of kilometres per side),
where the geological properties under ground have
little diversity. The search for general discriminants
135 is therefore biased, the discriminants only being
effective for a given region.

Moreover, as described in the document reference
[1], the events of the two classes to be discriminated
can come from two clearly distinct geographic regions,
140 sometimes as far apart as several hundreds of
kilometres. It is therefore impossible to know to what
extent the "colouring" of the signals by the geological
layers travelled through influences the discrimination,
rather than the signals themselves. But seismologists
145 know that this "colouring" is far from negligible and
that localisation information is very important.

Generally, a very limited number of recording
stations is used. The signals are recorded by two or
three stations at maximum, but usually by only one
150 single station. The seismic event is thus represented

by a single signal, which reduces usable information considerably.

Finally, the events integrated into the data base are very generally selected according to previously
155 defined criteria: magnitude greater than a certain threshold, signal/noise ratio greater than a certain threshold, as described in document reference [2]. But this selection evidently biases the results completely.

Although prior art studies have made it possible
160 to register a wide range of potentially useful discriminants for classification, it has proved to be very difficult to find efficient global discriminants because of the high number of distinct types of blasting and earthquakes.

165 In most cases, the classifiers proposed turn out to be inefficient because they are too simple (linear separators) or impossible to regulate because of their complexity. They demand enormous work on pre-processing the data, which means that the systems proposed cannot
170 be generalised.

Example of seismic surveillance

The detection and geophysical laboratory (LDG) of the CEA has continuously surveyed the seismic activity
175 of the earth since 1962. When a seismic event occurs in any spot on the globe, it is recorded in France by a network of forty-two vertical seismometers located on mainland territory, as shown in Figure 1, the SP stations being short-period stations and the LP
180 stations being long-period stations. A detailed description of the network of seismometers and the

propagation of seismic waves in France is given in the document reference [7].

This network, which since its creation, used
 185 transmission by Hertzian channels, has recently moved
 to digital transmission by satellite. Filtering and a
 gain adapted to the signal make it possible to detect
 close earthquakes or on the other hand longer period
 distant earthquakes called teleseisms. The regulation
 190 of filtering parameters and gain must make it possible
 to find a compromise between the detection of seismic
 events of relatively low magnitude and background
 noise.

Figure 2 shows signals recorded by seismometers of
 195 the LDG laboratory located between 84 and 146
 kilometres (that is SBF: 84 km; PGF: 110 km; FRF:
 127 km; LMR: 136 km and LRG: 148 km) from the estimated
 epicentre of an earthquake of magnitude 1.9 located 10
 kilometres south of Imperia in Italy on May 9, 1996
 200 (time: 1hr 0min 59sec; latitude: 43.34; longitude:
 8.19; magnitude: 1.9).

Different seismic phases are indexed on each
 signal, which will be used for the detailed analysis of
 the event.

205 Each year, about 9,000 close seismic events are
 thus detected, of which 800 to 1,200 are natural
 earthquakes.

The seismologists of the LDG laboratory process
 and analyse daily the data recorded by the stations of
 210 the French network. They publish a weekly bulletin
 containing the whole of the natural earthquakes in
 France or in the bordering regions. A similar bulletin

is published for teleseisms. Table I, given at the end
of the description, is an extract from the bulletin for
215 the period from September 9 to 15, 1998. In this table,
there are the following abbreviations:

TIME OR. : time of origin (TU);
LAT : latitude of the epicentre (deg.);
LON : longitude of the epicentre (deg.);
220 DEP : depth of the epicentre (km);
LM : local magnitude;
MSE : mean square error (s).

This table thus comprises the ensemble of close
earthquakes detected during this week and the
225 characteristics of each event: date and time of origin,
position and depth of the epicentre, magnitude, mean
square error for the localisation and deduced
localisation region.

Because of the great imbalance between the number
230 of artificial events and that of natural events (in
France, seismic events of artificial origin are ten
times more frequent than natural seismic events), only
events presumed to be earthquakes or events of non-
determined class are extracted from the background
235 noise by seismologists in order to be analysed more
precisely later by a localisation software. The other
signals (mainly artificial events) are archived for six
months.

The procedure for analysing the signals comprises
240 an already automated localisation, followed by a
characterisation phase (determination of the event at
the origin of the signals).

The analysis of the signals is carried out using a global system illustrated in Figure 3.

245 The aim of the invention is to compensate for the inconveniences of prior art systems by proposing a new system of artificial intelligence for classifying events, objects or situations from signals and discriminant parameters produced by models.

250

Description of the invention

The present invention relates to a system of artificial intelligence for the classification of events, objects or situations from signals and discriminant parameters produced by models, characterised in that it comprises at least one processing branch comprising a fuzzy expert system (FES expert) taking a decision according to high level properties and lower level discriminant parameters extracted from signals by signal processing type procedures, and capable of explaining its decision to the user through the intermediary of rules selected by order of applicability.

265 In this fuzzy expert system a gradient decrease is carried out on the parameters:

- $x = y/\sigma$
- $s = \ln/2\sigma^2$
- $r = \ln (\rho)$
- d

270 with:

- y : position of fuzzy sets of premises
- σ : width of fuzzy sets of premises
- ρ : weight of rules

• d: degree of activation of each class for each
275 rule.

Advantageously the system according to the invention is a multi-expert system constituted of at least two independent processing branches, organising themselves automatically through statistical learning
280 on the data bases, having particular properties, and merged by a high level decisional system. Advantageously one branch comprises a neuro-fuzzy classifier (NFC expert) taking its decisions from high level properties and lower level discriminant
285 parameters extracted from signals by signal processing type procedures. Advantageously another branch comprises a neural network with local connections and shared weights (TDNN) constituted of banks of non-linear adaptable filters, itself extracting
290 discriminant information for time-frequency representation of the signals corresponding to the event.

The invention can be used in different fields of application and particularly in:

295 • *Surveillance of geophysical events*

The system then applies to the analysis of any geophysical event observable through signals received by the stations:

- seismic signals;
- 300 - infrasound;
- hydro-acoustic waves.

These events can be close events (called regional) or distant events (for example, teleseisms).

The function to be ensured may be:

305 - filtering to eliminate the non-relevant events
for later processing;
 - detection of special events;
 - exhaustive classification into a set of groups
of events of the same nature.

310 • *Industrial surveillance and monitoring*

The system also applies to the analysis of objects
or industrial processes, as long as one has available
signals or images collected by sensors. A few examples
are given below:

315 • Quality control of manufactured objects or
products: the aim is to verify the shape and/or
position of objects, to detect and characterise
defects. The NFC and FES detectors use measurements
produced by image processing. The TDNN expert uses one
320 or several images of the part.

 • Predictive maintenance of equipment: the aim is
to foresee a future failure of machines, computers,
electronic equipment, sensors in order to give a
warning and make it possible to implement a correction
325 procedure before breakdown. The NFC and FES experts use
measurements of high level coefficients, and
correlations. The TDNN expert uses signals.

 • Complex process surveillance: the aim is to
verify that a production chain is operating correctly.
330 NFC and FES experts use measurements of high level
coefficients. The TDNN expert uses measurements of low
level coefficients.

In the geophysical domain, the high level
properties can be the location, the magnitude, the time
335 and the date. The system according to the invention

makes it possible to carry out automatic classification of seismic events into three sets:

- natural earthquakes;
- explosions (blasting in mines and military trials);
- rock bursts (collapse of layers in mines).

The system then integrates into a chain of automatic processing to operate a filtering function of seismic events. Its principal characteristics are:

- maximum reliability: the system is able to take decisions even with corrupted or imprecise data, or even in the absence of certain information;
- access to the explanation of decisions in order to avoid any eventual doubt about a decision.

Brief description of the drawings

380

Detailed description of embodiments

General description of the system

385 The system according to the invention comprises at least one processing branch containing a fuzzy expert system. When it comprises several branches of independent processing, one refers to a multi-expert system.

• *Multi-expert decision making*

390 The principle of multi-expert decision-making, which is thus one of the embodiments of the invention, is the exploitation of the synergy between several complementary processing branches. This complementarity resides in:

395 A. The general performances: one branch is rather generalised (fairly good performances in most cases), another is rather specialised (very good performance for certain difficult cases, a

higher level of errors in cases outside its competence).

- 400 B. The performances according to the case treated:
 one branch can be more able than another for
 treating a particular case.
- C. The nature of inputs (high level signals or
 data).
- 405 D. The nature of outputs (single data for the
 class, estimation of the certitude of the
 decision, formal explanation of the decision).

Figure 4 shows the diagram of the principle of the
 multi-expert system for discrimination of seismic
 410 events according to the invention. This system is
 constituted of several independent processing branches,
 each with special properties, merged by a high level
 decisional system.

These branches are:

- 415 - a neuro-fuzzy classifier, NFC, making its
 decisions from high level properties of events (for
 example for seismic events: localisation, magnitude,
 time, day of the week) and lower level parameters
 extracted from the signals by procedures of the signal
 420 processing type;

- a fuzzy expert system, FES, taking a decision in
 an independent way from the same information, and able
 to explain its decision to the user through the
 intermediary of rules selected by order of
 425 applicability to the event being processed;

- a neural network with local connections and
 shared weights, TDNN, constituted of banks of non-
 linear adaptable filters, itself extracting the

relevant information for time-frequency representations
 430 from signals corresponding to the event.

These three branches configure themselves automatically by statistical learning on the data bases of seismic events.

- *Learning from examples*

435 Learning from examples consists of building a model of the decision-making system by progressive adjustment of parameters based on data. This model must be able to associate the right decision (output) to a set of data describing the case being processed
 440 (inputs). This is carried out progressively, by iterative presentation of cases available in the example base inputting the system. Such a procedure is shown in the flow chart of figure 5.

According to the invention, the learning model can
 445 either be a network of artificial neurons or a fuzzy expert system.

Once the system has ended its learning phase, its internal parameters are set and the system is ready for use.

- 450 • *Neural network of the "multilayer Perceptron" type*

Such a network of artificial neurons of the "multilayer Perceptron" type is a special model of a neural network able to be used as a decision-making system. It is constituted of a network of robots for
 455 simple calculations, "artificial neurons".

A neuron N^j , as shown in figure 6, is an entity constituted of a weight-vector $\mathbf{W}_j = \{w_{ij}\}$ and a non-linear transfer function ϕ . It allows a vector input $\mathbf{X} = \{x_i\}$

and carries out a transformation of these inputs of the

460 type $y_j = \phi\left(\sum_i w_{ij}x_i\right).$

Similar to the vocabulary used in neurophysiology, one says that each input x_i is linked to the neuron N^j by a synaptic connection. A synaptic weight w_{ij} modulates the efficiency of this connection.

465 In a network of artificial neurons, as shown in figure 7, the neurons are assembled in successive layers. A layer is defined as a set of neurons not having connections between each other, but able to have connections with neurons of the preceding layers (inputs) or following layers (outputs). In general, only neurons of successive layers are connected.

Learning consists of progressively modifying the weights values w_{ij} until the outputs of the network, which is constituted of a certain number of neuron layers, correspond to the required outputs.

In order to achieve this, one defines a classification error one wishes to minimise. The most commonly used error is the mean square error, defined

by $E = \sum_{k=1}^{N_{\text{outputs}}} (z_k - z_k^{\text{required}})^2$. The method consists of making a

480 gradient decrease on the weights by the equation

$\Delta w_{ij} = -\alpha \frac{\partial E}{\partial w_{ij}}$ with $\alpha > 0$. This equation, when developed, provides the correction formula for each weight of the network.

- *Fuzzy expert system*

485 A fuzzy expert system is another system model for decision-making. It has the advantage over a neural

network of giving a form of explanation for its decisions. It is constituted of a set of calculation units, the "fuzzy inference rules".

490 A fuzzy inference rule is an entity of the form "if <premise> then <conclusion>". The premise is the part sought to put into correspondence with the input data.

495 In fact, a fuzzy set is a set whose borders are progressive, contrary to a classic set, which has defined borders. Thus an element is more or less part of each fuzzy set. When the data are of dimension 1, a classic set can be represented by a rectangle (membership=1 inside, 0 outside), whereas a fuzzy set
500 can be a triangle, a trapezium a Gaussian form..

 In the same way as above, learning consists of modifying progressively the parameter values until the outputs of the fuzzy expert system correspond to the required outputs.

505 Four types of parameters are calculated by learning: the position and width of the fuzzy sets of premises, the weights of the rules and the degree of activation of each class for each rule.

 In the operational utilisation phase, the fuzzy
510 expert system provides, besides the class attributed to a seismic event, the list of rules applicable by descending order of relevance. Some of these rules can be in contradiction with the others, which makes it possible to examine alternative solutions, but it is
515 the aggregation of the result of all the rules which provides the overall result.

Therefore, at the disposal of the user, there exists:

- the initial decision (earthquake, explosion, 520 rock burst);
- the list of applicable rules;
- the list of rules in contradiction to this decision;
- the reason for the decision of each rule 525 (through examination of the coherence between the data and the corresponding fuzzy sets).

An example of decision rule found by the system is given below:

530 if (Time is the *middle* of the afternoon)
 and (Latitude is *very close* to 43.5°N)
 and (Longitude is *very close* to 5.5°E)
 and (Magnitude is *about* 2.7)
 and (Date is *preferably* Saturday)
 then (with level of confidence=0.8)
 535 (earthquake is improbable)
 (explosion is probable)
 (rock burst is improbable).

In the invention, for reasons of difficult convergence, this gradient is parameterised by 540 introducing intermediate variables. If one wishes to carry out a gradient decrease on a parameter p with $p=\phi(s)$, ϕ being a differentiable function, strictly monotonic, independent from p and values of examples serving for learning, one has the same final solutions 545 by carrying out a gradient decrease on s . The advantage of such a change of variable is that it becomes possible to change the way of reaching the solution,

and in particular to facilitate convergence in difficult cases.

550 In the invention, the following parameters are optimised:

(1) The position y of the fuzzy sets of premises: when the gradient decrease is applied directly on this parameter, one generally obtains difficult convergence.
 555 This is explained by the fact that the variation of the position y of the fuzzy sets of premises is not an increasing function of the distance from the example. This phenomenon is corrected by posing $x=y/\sigma$.

(2) The width σ of the fuzzy sets of premises:
 560 when the data are structured in sets of very different sizes, the algorithm cannot converge. By studying the relative variation σ/σ , one discovers that it is not bounded (that is to say that nothing prevents it tending towards infinite values). When the data are
 565 very grouped, this variation does in actual fact take very high values. In order to have a lower relative modification when the data are close, one poses $s=\ln(2\sigma^2)$.

(3) The weights p of the rules: this is the most
 570 difficult parameter to set. With a direct gradient decrease, the lowest weights diminish and become negative, which makes them lose all significance and makes the algorithm diverge. Thus one chooses a function for positive activation by imposing a
 575 supplementary restriction: for different examples with the same activation level of the rule, the variation of this level must be the same if the conclusions are equal. The consequence is that the relative variation

of the weights of the rules must be constant when the
 580 examples have the same degree of belonging to the fuzzy
 sets. This is carried out by posing $r=\ln(\rho)$.

(4) The degree of activation d of each class for
 each rule.

The gradient decrease is thus carried out not on
 585 y , σ and ρ , but on:

- $x=y/\sigma$
- $s=\ln(2\sigma^2)$
- $r=\ln(\rho)$

For d , one does not carry out any change of variable.
 590 These changes in variables ensure very good quality of
 convergence and allow very efficient fuzzy expert
 systems to be obtained.

• *Base of examples and validation*

The base of examples used must verify two
 595 fundamental principles:

- to be *qualitatively* representative of the real
 problem (distribution of examples in conformity with
 the real distribution);
- to be *quantitatively* representative of the
 600 problem (number of examples sufficient to constitute a
 satisfactory sampling).

There are several methodologies for learning and
 validation. In the simplest procedure, one divides the
 base of examples into two disjointed bases: the learning
 605 base and the test base. One trains the system by
 learning on the first and one verifies its correct
 operation on the second. A base of examples that does
 not conjointly verify the two properties mentioned
 above runs the risk of leading to a system incapable of

610 generalising correctly, that is to say of operating on
new examples, not presented during the learning stage.

Whether it concerns artificial neuron networks,
fuzzy expert systems or more generally any system
conceived by statistical learning on experimental data,
615 it is of prime importance to use a base of examples
which is adequate in quality and in quantity, and to
validate the system produced by rigorous procedures.

Detailed description

620 • *Description of a seismic event*

A seismic event to be identified can be described
by:

- the signals data coming from the network of
seismic stations, or
- 625 - highest level properties, measurable directly or
calculated by geophysical models. For example, one can
use the location of the event (latitude and longitude),
its magnitude and the moment it occurred (time and day
of the week). For example the high level information is
630 as follows: Thursday 7 April 1966 at 12hr, an
earthquake of magnitude 1.4 occurred at longitude
02°35'06" East and latitude 49°12'25" North.

• *The neuro-fuzzy classifier*

The neuro-fuzzy classifier (NFC expert), as shown
635 in figure 8, is constituted of a neuro-fuzzy coding of
the data followed by a multilayer perceptron. It is
applicable to high level data.

Neuro-fuzzy coding consists of associating several
coding cells to each input variable (or set of input
640 variables), each cell having a region of influence

modelled by a function defining its activation mechanism. The presentation of a vector of values then generates an activation diagram for the associated coding cells.

645 Figure 9 shows this mechanism for activating coding cells. Presentation of a value generates an activation diagram corresponding to the impulse response of each activation function to the value presented. The levels of grey attributed to the centres
650 of the cells indicates their activation level comprised between 0 and 1 (black: 1, white: 0).

Figure 10 shows examples of activation diagrams generated by presentation of typical values. It concerns a coding of cursor type. The low values (or
655 high respectively) preferentially activate the left cells (or right respectively).

The interests of this coding are multiple:

- by its very nature, it makes it possible to represent incomplete, imprecise or uncertain data and
660 to use them efficiently for the decision-making;
- by its non-linear processing properties of data, it facilitates later processing (here, the classification).

This neuro-fuzzy coding is carried out in several
665 successive stages: definition of sub-groups of characteristics, choice and placing of coding cells assigned to each group, definition of parameters for the region of influence of each cell. The details of this procedure are explained in document reference [8].

670 Once the data have been coded, they are analysed
by the multilayer perceptron which then calculates the
class.

- *The fuzzy expert system*

675 In an embodiment the system according to the
invention comprises a single processing branch based on
such a fuzzy expert system.

The fuzzy expert system (FES expert) is also
applicable to high level data.

680 In figure 11, a fuzzy expert system with five
rules is shown (one rule per line).

For each line, the five columns on the left
represent the premises and correspond to five entries:
time, latitude, longitude, magnitude and date. The
premises are composed of fuzzy sets in Gaussian form
685 which cover the domains of the input variable leading
to reinforcement of the activity of the rule.

Four types of parameters are calculated by
learning: the position and the width of the fuzzy sets
of premises (columns 1 to 5), the weights of the rules
690 (column 6), which makes it possible to specify the
degree of importance of each rule in the decision
process, and the degree of activation of each class
(natural earthquake, explosion or rock burst) for each
rule (columns 7 to 9).

695 Each time an example to be classified is
presented, a calculation is made of the contents of
column 10 and column 6:

- Column 10 gives the activation of each rule (and
thus enables estimation of its fit with the case being
700 processed).

• Line 6 is the synthesis of the decisions from the five rules and gives the overall response of the fuzzy expert system (here, the decision is "explosion"). This synthesis is made by calculating the barycentre of the decisions from all the rules (columns 7 to 9) weighted by the corresponding activation level (column 10). In figure 11, the position of the barycentre for each class is symbolised by a vertical trace line 6, columns 7 to 9.

Learning is carried out in two stages:

- a first phase consists of positioning the fuzzy sets (centres and widths), for example by means of an algorithm called fuzzy C-averages, as described in document reference [9];

- a second phase consists of producing a gradient decrease on the four types of parameters.

- *Neural network with local connections and shared weights*

Contrary to the two preceding branches, the neural network with local connections and shared weights (TDNN expert) allows input of the seismic signals themselves and learns to extract by learning not only the decision procedure, but also the discriminant parameters which will serve as base for this decision. This neural network is of the multilayer perceptron type with local connections and shared weights taking as input the pre-processed spectrograms of seismic signals, as described in document reference [10]. These spectrograms are obtained by applying a sliding window Fourier transform on the signal.

Figures 12A to 12D show the successive pre-processing applied to each seismic signal, resulting in a final spectrogram with 15 frequency bands: figure 12A shows the initial signal; figure 12B shows the spectrogram deduced from the signal with 50 frequency bands; figure 12C shows the "noise-suppressed" spectrogram; figure 12D shows the spectrogram after reduction from 50 to 15 frequency bands.

The spectrogram obtained is then pre-processed and next presented as input for a neural network of the TDNN type. Each network is specialised in the treatment of signals recorded by a given station.

Figure 13 shows the architecture of a TDNN network specialised in classification of spectrograms deduced from signals recorded by a given seismometer, this network comprising four neuron layers. The input layer has local connections and shared weights (4 frames with a delay of 2 frames) with the first hidden layer. The latter also has local connections with shared weights (9 frames with a delay of 5 frames) with the second hidden layer, totally connected to the last layer.

The shared weights make the architecture stronger for small differences in phase recordings or missing or erroneous frames. However, because of the speed of propagation of the P waves (compression) and S waves (shearing), the time between the arrival of phase P and phase S varies in function of the distance between the recording station and the epicentre of the event, which complicates learning. The solution adopted consists of aligning the recording of phase P on the 10th frame and that of phase S on the 60th frame.

• *Final decision making*

For the final decision-making, it is assumed that all the outputs are comprised within the real interval[-1,1]. This decision-making consists of an association of answers provided by the three branches in order to increase reliability. In can be carried out by a calculation of mathematical averages on the homologous outputs of each of the three branches. For each of the three outputs S_i of the overall system one then has:

$$S_i = \frac{1}{3} \sum_{j=1}^3 S_{ij}$$

The certitude of the answer is evaluated by a coefficient calculable only if the system is in a situation for decision-making (that is to say if there is one and a single strictly positive output). This coefficient is then equal to the average of the absolute values of the outputs:

$$K = \frac{1}{3} \sum_{i=1}^3 |S_i|$$

- $K < 0.2$: doubt
- $K \in]0.2, 0.4]$: caution
- $K \in]0.4, 0.6]$: reasonable certainty
- $K \in]0.6, 0.8]$: high certainty
- $K > 0.8$: almost absolute certainty

Thus, for example, one can obtain:

System	Class chosen	Details of responses per class	Degree of certainty
1	Class 3	(-0.9 -0.4+0.8)	0.7 high certainty
2	Undetermined 1 or 3	(+0.1 -0.5+0.3)	Complete uncertainty
3	Class 1	(+0.2 -0.6-0.2)	0.3: caution
Fusion	Class 3	(-0.2 -0.5+0.3)	0.3: caution

Example of implementation of the invention:
discrimination of regional seismic events

790 • *Localisation of the event*

The discrimination "natural event / artificial event" is a major step in seismic surveillance, carried out rapidly from reading the signals during the reduction stage, and then improved with each new processing. It is estimated that nearly seven years are needed for analysts to become completely operational. Since these analysts are real experts, it is difficult to describe their reasoning method clearly, since it is based both on expert know-how and on case-by-case reasoning.

The location of a seismic event is obtained after a succession of exchanges between two principal stages:

- the recording of the different seismic phases carried out on signals registered by stations detecting the event and the calculation of the magnitude;
- the localisation itself, carried out by a mathematical model created by seismologists.

After the recording stage, the localisation of the event can be carried out using a simulation software known to those skilled in the art. It uses

seismological models containing information about the speed of waves, the different types of waves and their propagation mode, altitude corrections according to stations etc. Several localisation hypotheses are
 815 proposed, associated to a degree of data consistency. If they do not satisfy the expert, he modifies his phase recordings and then restarts a localisation search. This cycle is repeated until a result considered to be satisfactory is obtained.

820 The quality of the localisation depends on the number and quality of the stations used for localising the event, together with their azimuth distribution. In general, events located in France are better localised than events abroad. To improve localisation in the
 825 latter case, experts regularly consult data from abroad. With French data alone, the precision of localisation of events in France is on average five kilometres. In the best of cases, it is estimated at about one kilometre.

830 Table II at the end of the description gives an example of the results provided by the localisation procedure. The upper part resumes the results obtained: for each value of time of origin, of magnitude and localisation (latitude-longitude) an estimated level of
 835 inaccuracy is associated. The lower part names the stations taken into account for the localisation and the mean square errors (MSE) obtained as a function of the hypothesis of epicentre depth. In the case of rock bursts, the depth is set arbitrarily at a depth of one
 840 kilometre.

- *Characterization of the event*

Here we are concerned by local and regional seismic events, meaning those in mainland France or adjacent regions. These events are often described as
 845 close as opposed to distant teleseisms (epicentre situated at several thousands of kilometres from the sensor).

Three types of seismic events have to be discriminated:

- 850 - earthquakes, seismic events of natural origin;
- terrestrial explosions (blasting in mines, quarries, work-sites etc.) or in the sea (bomb disposal, weapons testing etc.);
- rock bursts corresponding to the collapse of a
 855 mining layer and associated with the operation of the mine.

Analysis of the state of the art has demonstrated the failure of approaches based on discrimination relying on seismic signals alone. Thus one needs to use
 860 all the available data by adopting an approach based on multi-expert and multi-source merging. The concept of the system of automatic discrimination of seismic events is based on three modules:

- the first two (NFC and FES experts) are modules
 865 carrying out discrimination from high level data only, deduced by the inverse model of the LDG laboratory. Thus, at this level, no seismic signal is taken into account directly;
- the third (TDNN expert) is based on the analysis
 870 of the seismic signals.

• *Data used*

geographic spread of events:

The seismic events to be analysed are spread over the whole of French mainland territory and an adjacent perimeter. The epicentres of the events recorded by the LDG laboratory between 1962 and 1996 are shown in figure 14.

high level data:

Each seismic event is characterised by the following information: the date and time of origin of the event, the latitude and longitude of the epicentre, and its magnitude.

The time and the date are stored because of the rules about quarry or mine blasting in France, forbidding blasting at night or during weekends or public holidays. Nonetheless, permission is given for certain work-sites, for example to avoid disturbing traffic.

The magnitude is recorded since, according to seismologists, rock bursts reach a typical magnitude (about 3). Furthermore, only earthquakes can produce greater magnitudes. Several values of magnitude are taken into account when they are available.

The localisation of the epicentre, characterised by its latitude and its longitude, is also a major characteristic. However, there are certain mines located in regions of high seismicity and capable of provoking rock bursts.

low level data:

Low level data are signals arriving from the 42 seismic stations of the LDG laboratory (see figure 1). The pre-processing relates essentially to the creation of spectrograms of seismic signals, which are non-

stationary. These spectrograms are obtained by
 905 application of a sliding window Fourier transform on
 the signal. To begin with, the signal sampled at 50 Hz,
 is segmented into two-second frames delayed by one
 second by a Hamming code window. Next, the spectral
 energy density is calculated for 50 frequency bands,
 910 eliminating the continuous component. Then a
 logarithmic transformation is applied with noise
 suppression, with a supposedly logarithmic model, in
 each band according to the equation $\max(\ln(1+x) -$
 $\mu(\text{noise}) - \sigma(\text{noise}), 0)$, where $\mu(\text{noise})$ and $\sigma(\text{noise})$
 915 correspond to the average and the deviation type of the
 noise estimated over a period anterior to the recording
 of the wave P. Finally, the number of frequency bands
 is reduced from 50 to 15 through a pseudo-logarithmic
 compression of high frequencies.

920 • *Results obtained*

The system described above classifies French
 regional seismic events with the following level of
 performance:

- 86% for earthquakes;
- 925 - 91% for explosions;
- greater than 99% for rock bursts.

The overall level of performance is about 90%.

Amended claims to file when entering the National Phase

CLAIMS

1. System of artificial intelligence for classification of events, objects or situations from signals and from discriminant parameters produced by models, comprising at least one processing branch
 5 comprising a fuzzy expert system taking a decision according to high level properties and discriminant parameters of lower level extracted from signals by signal processing type procedures, and capable of explaining its decision to the user through the
 10 intermediary of rules selected by order of applicability.

2. System according to claim 1 in which, in the fuzzy expert system a gradient decrease is carried out
 15 on the parameters:

- $x = y/\sigma$
- $s = \ln/2\sigma^2)$
- $r = \ln (p)$
- d

20 with:

- y : position of fuzzy sets of premises
- σ : width of fuzzy sets of premises
- p : weights of rules
- d : degree of activation of each class for
 25 each rule.

3. System according to claim 1, which is a multi-expert system constituted of at least two independent

Amended claims to file when entering the National Phase

processing branches, organising themselves automatically through statistical learning on data bases, having particular properties and merged by a high level decisional system.

5

4. System according to claim 3, in which one branch comprises a neuro-fuzzy classifier taking its decisions based on high level properties and lower level discriminant parameters extracted from signals by
10 signal processing type procedures.

5. System according to claim 3, in which one branch comprises a neural network with local connections and shared weights constituted of banks of
15 non-linear adaptable filters, itself extracting discriminant information for time-frequency representation of the corresponding signals.

6. System according to claim 1, which is a system
20 for classification of geophysical events.

7. System according to claim 6, in which the high level properties are the localisation, the magnitude, the time and the date.

Declaration, Power Of Attorney and Petition

WE (I) the undersigned inventor(s), hereby declare(s) that :

My residence, post office address and citizenship are as stated below next to my name,

We (I) believe that we are (I am) the original, first, and joint (sole) inventor(s) of the subject matter which is claimed and for which a patent is sought on the invention entitled

SYSTEM OF ARTIFICIAL INTELLIGENCE FOR THE CLASSIFICATION OF EVENTS, SUBJECTS OR SITUATIONS
FROM SIGNALS AND DISCRIMINANT PARAMETERS PRODUCED BY MODELS

the specification of which

- ☐ is attached hereto.
- ☐ was filed on
as Application Serial No.
and amended on
- ☒ was filed as PCT international application
Number PCT/FR00/01804
on June 28, 2000
and was amended under PCT Article 19
on May 11, 2001

We (I) hereby state that we (I) have reviewed and understand the contents of the above-identified specification, including the claims, as amended by any amendment referred to above.

We (I) acknowledge the duty to disclose information known to be material to the patentability of this application as defined in Section 1.56 of Title 37 Code of Federal Regulations.

We (I) hereby claim foreign priority benefits under 35 U.S.C. § 119 (a)-(d) or § 365 (b) of any foreign application(s) for patent or inventor's certificate, or § 365 (a) of any PCT International application which designated at least one country other than the United States, listed below and have also identified below, by checking the box, any foreign application for patent or inventor's certificate, or PCT International application having a filing date before that of the application on which priority is claimed. Prior Foreign Application (s)

Application No.	Country	Day/month/Year	Priority Claimed	
99 08472	FRANCE	01 JULY 1999	<input checked="" type="checkbox"/> YES	<input type="checkbox"/> NO
_____	_____	_____	<input type="checkbox"/> YES	<input type="checkbox"/> NO
_____	_____	_____	<input type="checkbox"/> YES	<input type="checkbox"/> NO
_____	_____	_____	<input type="checkbox"/> YES	<input type="checkbox"/> NO

We (I) hereby claim the benefit under Title 35, United States Code, § 119 (e) of any United States provisional application(s) listed below.

And we (I) hereby appoint :William L. Mathis, Registration Number 17,337; Alan E. Kopecki, Registration Number 25,813; Eric H. Weisblatt, Registration Number 30,505; Peter H. Smolka, Registration Number 15,913; Regis E. Slutter, Registration Number 26,999; James W. Peterson, Registration Number 26,057; Robert S. Swecker, Registration Number 19,885; Samuel C. Miller III, Registration Number 27,360; Terasa Stanek REA, Registration Number 30,427; Platon N. Mandros, Registration Number 22,124; Ralph L. Freeland Jr., Registration Number 16,110; Robert E. Krebs, Registration Number 25,885; Benton S. Duffett Jr., Registration Number 22,030; Robert M. Schulman, Registration Number 31,196; Joel M. Freed, Registration Number 25,101; James A. Labarre, Registration Number 28,632; William C. Rowland, Registration Number 30,888; Norman H. Stepno, Registration Number 22,716; E. Joseph Gess, Registration Number 28,510; Richard H. Kjeldgaard, Registration Number 30,186; Ronald L. Grudziecki, Registration Number 24,970; David D. Reynolds, Registration Number 29,273; T. Gene Dillahunt, Registration Number 25,423; Frederick G. Michaud Jr, Registration Number 26,003; R. Danny Huntington, Registration Number 27,903 and Anthony W. Shaw, Registration Number 30,104; our (my) attorneys, with full powers of substitution and revocation, to prosecute this application and to transact all business in the Patent Office connected therewith; and we (I) hereby request that all correspondence regarding this application be sent to the firm of BURNS, DOANE, SWECKER & MATHIS, whose post Office Address is : George Mason Building, Washington and Prince Streets, P.O. Box 1404 Alexandria, Virginia 22313-1404.

We (I) declare that all statements made herein of our (my) own knowledge are true and that all statements made on information and belief are believed to be true ; and further that these statements were made with the knowledge that willful false statements and the like so made are punishable by fine or imprisonment, or both, under Section 1001 of Title 18 of the United States Code and that such willful false statements may jeopardise the validity of the application or any patent issuing thereon.
